Chunghyuldan (Daio-Orengedokuto in Japanese) (CHD) has been used as an antihyperlipidemic and antiischemic agent in Korea. To evaluate in vitro the efficacy of Chunghyuldans (CHDs) metabolized with and without human intestinal microflora against brain ischemia, we investigated its anti-inflammatory effect on LPS-induced RAW264.7 cells. Both metabolized CHD (MCHD) and CHD showed antioxidant activities in vitro, and inhibited nitric oxide (NO) and prostaglandin E2 (PGE2) productions in lipopolysaccharide (LPS)-induced RAW264.7 cells. These also inhibited enzyme activities and protein expressions of inducible NO synthase and cyclooxygenase-2 in LPS-induced RAW264.7 cells. MCHD-inhibitory activity against NO and PGE2 productions in LPS-induced RAW264.7 cells was more potent than those of CHD. These results suggest that CHD may show potent anti-inflammatory activity in vivo and can improve brain ischemia.

Key words Chunghyuldan; Daio-Orengedokuto; nitric oxide; prostaglandin E2; cyclooxygenase (COX)-2; ischemia

MATERIALS AND METHODS

Materials N\textsubscript{G}-Monomethyl-L-arginine (L-NMMA), LPS, caffeic acid, allopurinol and indomethacin were all purchased from Sigma Chemical Co. (U.S.A.). The Griess reagent was purchased from Promega Co. (U.S.A.). The PGE2 enzyme immunoassay kit and bovine COX Inhibitor Screening Assay kits were purchased from Cayman Chemical (U.S.A.). Chunghyuldan (CHD) was prepared according to the previous method. It consists of 80% EtOH extracts of Coptidis Rhizoma 4 g, Phellodendri Cortex 4 g, Scutellariae Radix 4 g, Gardeniae Fructus 4 g, and Rhei Rhizoma 4 g.

Metabolized CHD (MCHD) was prepared by incubating CHD with intestinal microflora as follows. CHD (2 g) was incubated with human intestinal bacteria at 37 °C for 24 h, extracted with ethyl acetate and concentrated. Each concentrate was used as a test sample in the present study, it also extracted with ethyl acetate and concentrated. Each concentrate was used as MCHD or CHD sample. CHD contained 1.2% berberine, 0.1% baicalin and 1.5% baicain when determined by HPLC. MCHD contained 0.9% berberine, 1.1% baicain and 0.2% baicalin.

Assay of Antioxidant Activities The 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging, superoxide anion radical generation and xanthine oxidase-inhibitory activities of CHD and MCHD were measured according to the method of Xiong et al. The nitric oxide was determined by measuring the amount of nitrite in the cell culture supernatant using Griess reagent according to the manufacturer’s protocol. The RAW 264.7 cells were stimulated with LPS (1 μg/ml) and test agents for 24 h, and briefly centrifuged and 150 μl of cell culture supernatant were mixed with 150 μl of Griess reagent, and incubated for 10 min at room temperature (light protected). The absorbance was measured using an ELISA reader at 540 nm and compared to a standard calibration curve prepared from sodium nitrite.

Assay of PGE2 The RAW 264.7 cells were seeded at 5 × 10\textsuperscript{4} cells per well in flat-bottomed 96-well plates. The test
agents and LPS (1 μg/ml) were added to the culture medium, and incubated at 37°C for 20 h. The medium was collected in a microfuge tube and then centrifuged at 2800×g for 10 min. The supernatant was decanted into a new microfuge tube, and the amount of PGE2 determined using a PGE2 Enzyme-Immuno-Assay kit (Cayman Chemical, U.S.A.).

**Measurement of iNOS Activity** The RAW 264.7 cells were stimulated with LPS (1 μg/ml) for 16 h, and the cells washed twice with PBS. They were then incubated with test agents or L-NMMA for 16 h. Cells were briefly centrifuged and 150 μl of the supernatant mixed with 150 μl of Griess reagent, and incubated 10 min at room temperature (light protected). The absorbance was measured using an ELISA reader at 540 nm, and compared to a standard calibration curve prepared from sodium nitrite.13)

**Measurement of COX-2 Activity** RAW 264.7 cells were seeded at 5×10^5 cells per well in flat bottomed 96-well plates. Cells were stimulated with LPS (1 μg/ml) for 16 h to induce COX-2. The cells were washed twice with fresh culture medium and incubated with test agents for 10 min. The cells were washed further for 40 min in medium with 30 μM arachidonic acid. The supernatants were removed and assayed for prostaglandin E2 as described above.13)

**Western Blot Analysis of iNOS, COX-2 and NF-κB in LPS-Induced RAW 264.7 Cells** Western blot analyses of the iNOS, COX-2 and NF-κB were performed according to the method of Ishihara et al.14) The RAW 264.7 cells were plated in 60 mm culture dishes (3×10^6 cells), test agents and LPS (1 μg/ml) added to the culture medium, and the cells incubated at 37°C for 6—20 h. The cells were lysed on ice for 15 min in an hypotonic buffer, containing 10 mm Tris (pH 8.0), 1.5 mM MgCl₂, 1 mM DTT, 0.1% NP-40, 5 μg/ml pepstatin A and 5 μg/ml aprotinin, and centrifuged at 12000×g and 4°C for 15 min. The supernatant was used as the cytosol fraction for the Western blot assays for the iNOS and COX-2 protein expressions. The pelleted nuclei fractions for the Western blot assays of the NF-κB protein expression were resuspended in the extraction buffer, containing 10 mm Tris (pH 8.0), 50 mm KCl, 300 mm NaCl, 1 mM DTT, 5 μg/ml pepstatin A and 5 μg/ml aprotinin, and then lysed on ice for 30 min. The lysed nuclei fraction was centrifuged at 12000×g and 4°C for 30 min. The cell lysates (40 μg) were separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) under reducing conditions, and transferred to polyvinylidene difluoride (PVDF) membranes (Millipore, Hertfordshire) at 30 V for 2 h. The membranes were blocked with 2% skim milk in PBS, containing 0.05% Tween 20, and incubated for 2 h at room temperature, and for a further 2 h with anti-iNOS, anti-COX-2, anti-NF-κB antibodies as primary antibodies. After removing the primary antibodies, the membranes were washed three times with phosphate buffered saline (PBS), containing 0.05% Tween 20, and then incubated with a 1:2000 dilution of the secondary antibody conjugated to horseradish peroxidase for 1 h. The membranes were washed three times, and reaction products visualized using an ECL Western blot system.

**Statistical Analysis** All the data from the in vivo experiments were expressed as mean ± S.D. and statistical significance was determined using Student’s t-test.

### RESULTS

**Active Oxygen Radical Scavenging Activities of CHD and MCHD** The components of these herbal medicines orally administered are therefore inevitably brought into contact with intestinal microflora in the alimentary tract and can be transformed before they were absorbed from the gastrointestinal tract. Therefore, to understand the pharmacological effects of CHD orally administered, we incubated it with human intestinal microflora and extracted with ethyl acetate. And then active oxygen radical scavenging activities of CHDs was measured (Table 1). Active oxygen radical scavenging activities superoxide radical scavenging and lipid peroxidation-inhibitory activities of MCHD were more potent than those of nontreated CHD. Main components of intact CHD was berberine, baicalin and chrysophanol glycoside. However, main components of metabolized CHD (MCHD) was berberine, baicalin and chrysophanol. Thus, glycosides of CHD was transformed to their aglycones.

**Effect of CHDs on NO and PGE2 Production of the Murine Macrophage Cells Induced by LPS** To evaluate the antiinflammatory effects of CHDs, their inhibitory effects on NO and PGE2 production in LPS-stimulated cultures of the murine macrophages of the RAW 264.7 cells were examined. The stimulation of the RAW 264.7 cells with LPS induced NO production (Fig. 1). However, both MCHD and CHD at concentrations of 10 and 50 μg/ml weakly inhibited NO production in LPS-stimulated RAW 264.7 cells. However, the difference between MCHD and CHD was not significant. Stimulation of the RAW 264.7 cells with the LPS

Table 1. Antioxidant and Anti-lipid Peroxidation Activities of CHD and MCHD

Each data represents the mean of triplicate experiments. a) DPPH (1,1-diphenyl-2-picrylhydrazyl) free radical scavenging assay. b) Xanthine oxidase inhibitory assay. c) Superoxide anion scavenging assay. d) Not determined. CHD, Chunghyuldan; MCHD, metabolized Chunghyuldan.

**Fig. 1. Inhibitory Effect of CHD and MCHD on NO Production of LPS-Stimulated RAW 264.7 Cells**

The RAW 264.7 cells were stimulated with LPS (1 μg/ml) and test agents for 24 h, and briefly centrifuged. NO contents of the resulting supernatant were measured by Griess reagent. LPS, lipopolysaccharide; MC, metabolized Chunghyuldan; C, Chunghyuldan; L-NMMA, N°-monomethyl-L-arginine. All values are means±S.D. (n=3) *Significantly different from LPS-stimulated group (p<0.05).
also increased the synthesis of PGE2 (Fig. 2). Both MCHD and CHD potently suppressed PGE2 production in a dose-dependent manner. Therefore inhibitory effect of CHD and MCHD on COX-2 activity was also investigated (Fig. 3). Both MCHD and CHD potently inhibited COX-2 enzyme activities at 10 μg/ml. However, both CHD and MCHD weakly inhibit iNOS activity (Fig. 4). MCHD inhibited iNOS activity more potently than CHD.

Effect of CHD and MCHD on iNOS and COX-2 Protein Expression in LPS-Stimulated RAW 264.7 Cells

Whether CHD could affect the iNOS and COX-2 protein expressions was also examined. Stimulation of the RAW 264.7 cells with LPS resulted in accumulation of the iNOS protein, as determined by Western blot analysis (Fig. 5). Both CHD and MCHD reduced the levels of the iNOS protein in a dose-dependent manner. Densitometer scans of the respective blots showed that CHD and MCHD at concentrations of 10 and 50 μg/ml, the levels of the iNOS protein were reduced by 40 and 47%, and 46 and 60% respectively, compared with the control cells stimulated with LPS. Those of MCHD were not significantly different to those of CHD. These amounts of iNOS protein correlated with the reduced accumulation of nitrite.

Stimulation of the RAW 264.7 cells with LPS also induced the expression of the COX-2 protein. Both CHD and MCHD reduced the levels of the COX-2 protein by 22 and 33%, and 34 and 45%, respectively, compared with the control cells stimulated with LPS. These amounts of COX-2 protein expression were correlated with the reduced accumulation of PGE2.

The effect of CHD and MCHD on the activation of the nuclear transcription factor NF-κB, which promotes both iNOS and COX-2 protein expressions, was investigated. The NF-κB in the nuclei fraction was activated by LPS. However, both CHD and MCHD inhibited the activation of the NF-κB (Fig. 5). The CHD and MCHD at concentrations of 10 and 50 μg/ml reduced the levels of the activated NF-κB by 52 and 59%, and 54 and 65%, respectively, compared with the control cells stimulated with LPS. The amounts of activated NF-κB were correlated with the reduced accumulation of the iNOS and COX-2 proteins. Particularly, MCHD-inhibitory activity was more potent than that of CHD.

DISCUSSION

Most herbal medicines are administered orally as decoctions. Their components are therefore inevitably brought into contact with intestinal microflora in the alimentary tract. The intestinal bacteria may transform these components before they were absorbed from the gastrointestinal tract. Studies on the metabolism of the components by human intestinal microflora are of a great importance to an understanding of their biological effects.15,16) The constituents of CHD was also metabolized by human intestinal microflora. The transformation increased antioxidant action of CHD. Therefore, we metabolized CHD and compared its anti-inflammatory
effect to that of metabolized CHD.

The inflammatory reactions are modulated by macrophages as well as neutrophils. NO and prostaglandins are two pleiotropic mediators produced at inflammatory sites by constitutive and inducible NO synthases and COX-1 and COX-2. Both CHD and MCHD potently inhibited the PGE2 and NO biosynthesis in LPS-stimulated RAW 264.7 cells. These did not only inhibit the activities of COX-2 and iNOS, but also inhibited the activation of NF-κB transcription factor, which should regulate the iNOS and COX-2 gene expressions, on the RAW 264.7 cells stimulated with LPS. The inhibitory activity of MCHD was more potent than that of CHD. These results suggest that CHD and MCHD may express antiinflammatory activity by the direct inhibition of COX-2 and iNOS enzyme activities and the regulation of the signal transduction related to the activation of NF-κB.

CHD contained a lot of components, which can be also metabolized by intestinal microflora in human intestine. The constituents of the metabolized CHD, thus MCHD, may be easily absorbed into blood rather than those of CHD. For example, baicalein could be absorbed into the blood, and express antiinflammatory action. Based on these findings, we believe that in vivo pharmacological activity of CHD may be similar to that of MCHD, and CHD may show potent anti-inflammatory activity, and improve brain ischemia.
